

From totally nonnegative matrices to quantum matrices and back, via Poisson geometry

S. Launois* and T.H. Lenagan

Abstract

In this survey article, we describe recent work that connects three separate objects of interest: totally nonnegative matrices; quantum matrices; and matrix Poisson varieties.

Mathematics Subject Classification 2000: 14M15, 15A48, 16S38, 16W35, 17B37, 17B63, 20G42, 53D17

Keywords: totally positive matrices, totally nonnegative matrices, cells, Poisson algebras, symplectic leaves, quantum matrices, torus-invariant prime ideals

Introduction

In recent publications, the same combinatorial description has arisen for three separate objects of interest: $\mathcal{H}$ -prime ideals in quantum matrices, $\mathcal{H}$ -orbits of symplectic leaves in matrix Poisson varieties and totally nonnegative cells in the space of totally nonnegative matrices.

Many quantum algebras have a natural action by a torus and a key ingredient in the study of the structure of these algebras is an understanding of the torus-invariant objects. For example, the Stratification Theory of Goodearl and Letzter shows that, in the generic case, a complete understanding of the prime spectrum of quantum matrices would start by classifying the (finitely many) torus-invariant prime ideals. In [8] Cauchon succeeded in counting the number of torus-invariant prime ideals in quantum matrices. His method involved a bijection between certain diagrams, now known as Cauchon diagrams, and the torus-invariant primes. Considerable progress in the understanding of quantum matrices has been made since that time by using Cauchon diagrams.

The semiclassical limit of quantum matrices is the classical coordinate ring of the variety of matrices endowed with a Poisson bracket that encodes the nature of the quantum deformation which leads to quantum matrices. As a result, the variety of matrices is endowed with a Poisson structure. A natural torus action leads to a stratification of the variety via torus-orbits of symplectic leaves. In [4], Brown, Goodearl and Yakimov showed that there are finitely many such torus-orbits of symplectic leaves. Each torus orbit is defined by certain rank conditions

* The research of the first named author was supported by a Marie Curie European Reintegration Grant within the 7th European Community Framework Programme.

on submatrices. The classification is given in terms of certain permutations from the relevant symmetric group with restrictions arising from the Bruhat order.

The nonnegative part of the space of real matrices consists of those matrices whose minors are all nonnegative. One can specify a cell decomposition of the set of totally nonnegative matrices by specifying exactly which minors are to be zero/non-zero. In [34], Postnikov classified the nonempty cells by means of a bijection with certain diagrams, known as Le-diagrams. The work of Postnikov was then developed by Talaska [36], Williams [37], etc., and led to the definition of *positroid varieties* that have been recently studied by Oh [32] and Knutson, Lam and Speyer [23].

The interesting observation from the point of view of this work is that in each of the above three sets of results the combinatorial objects that arise turn out to be the same! The definitions of Cauchon diagrams and Le-diagrams are the same, and the restricted permutations arising in the Brown-Goodearl-Yakimov study can be seen to lead to Cauchon/Le diagrams via the notion of pipe dreams.

Once one is aware of these connections, this suggests that there should be a connection between torus-invariant prime ideals, torus-orbits of symplectic leaves and totally nonnegative cells. This connection has been investigated in recent papers by Goodearl and the present authors, [14, 15]. In particular, we have shown that the Restoration Algorithm, developed by the first author for use in quantum matrices, can also be used in the other two settings to answer questions concerning the torus-orbits of symplectic leaves and totally nonnegative cells. The detailed proofs of the results that were obtained in [14, 15] are very technical, and our aim in this survey, is to describe the results informally and to compute some examples to illuminate our results.

1 Totally nonnegative matrices

A matrix is *totally positive* (TP for short) if each of its minors is positive and is *totally nonnegative* (TNN for short) if each of its minors is nonnegative.

An excellent survey of totally positive and totally nonnegative matrices can be found in [10]. In this survey, the authors draw attention to appearance of TP and TNN matrices in many areas of mathematics, including: oscillations in mechanical systems, stochastic processes and approximation theory, Pólya frequency sequences, representation theory, planar networks, A good source of examples, especially illustrating the important link with planar networks (discussed below) is [35].

1.1 Checking total positivity and total nonnegativity

Let us start with an example.

Example 1.1. cf. [35]. Is the matrix

$$A := \begin{pmatrix} 5 & 6 & 3 & 0 \\ 4 & 7 & 4 & 0 \\ 1 & 4 & 4 & 2 \\ 0 & 1 & 2 & 3 \end{pmatrix}$$

totally nonnegative?

In order to check this by calculating all minors, we would have to calculate

$$\binom{4}{1}^2 + \binom{4}{2}^2 + \binom{4}{3}^2 + \binom{4}{4}^2 = 16 + 36 + 16 + 1 = 69$$

minors. In general, the number of minors of an $n \times n$ matrix is

$$\sum_{k=1}^n \binom{n}{k}^2 = \binom{2n}{n} - 1 \approx \frac{4^n}{\sqrt{\pi n}}$$

by using Stirling's approximation

$$n! \approx \sqrt{2\pi n} \frac{n^n}{e^n}.$$

This suggests that we do not want to calculate all of the minors to check for total nonnegativity. $\square$

Luckily, for total positivity, we can get away with much less. The simplest example is the 2×2 case.

Example 1.2. The matrix

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix}$$

has *five* minors: $a, b, c, d, \Delta = ad - bc$.

If $a, b, c, \Delta = ad - bc > 0$ then

$$d = \frac{\Delta + bc}{a} > 0$$

so it is sufficient to check *four* minors. $\square$

The optimal result is due to Gasca and Peña, [12, Theorem 4.1]: for an $n \times n$ matrix, it is only necessary to check n^2 specified minors.

Definition 1.3. A minor is said to be an *initial minor* if it is formed of consecutive rows and columns, one of which being the first row or the first column.

For example, a 2×2 matrix has 4 initial minors: a, b, c and Δ . More generally, an initial minor is specified by its bottom right entry; so an $n \times n$ matrix has n^2 initial minors.

Theorem 1.4. (*Gasca and Peña*) *The $n \times n$ matrix A is totally positive if and only if each of its initial minors is positive.*

There is no such family to check whether a matrix is TNN. However Gasca and Peña do give an efficient algorithm to check TNN, see the comment after [12, Theorem 5.4].

Figure 1: An example of a planar network (all edges are directed left to right)

1.2 Planar networks

We refer the reader to [35] for the definition of a planar network. Consider a directed planar graph with no directed cycles, m sources, s_i and n sinks t_j . See Figure 1 (taken from [35]) for an example.

Set $M = (m_{ij})$ where m_{ij} is the number of paths from source s_i to sink t_j . The matrix M is called the *path matrix* of this planar network.

Notation 1.5. The minor formed by using rows from a set I and columns from a set J is denoted by $[I \mid J]$.

Planar networks give an easy way to construct TNN matrices.

Theorem 1.6. (*Lindström's Lemma, [30]*) *The path matrix of any planar network is totally nonnegative. In fact, the minor $[I \mid J]$ is equal to the number of families of non-intersecting paths from sources indexed by I and sinks indexed by J .*

If we allow weights on paths then even more is true.

Theorem 1.7. (*Brenti, [2]*) *Every totally nonnegative matrix is the weighted path matrix of some planar network.*

Example 1.8. This example is taken from [35]. The path matrix

$$M = \begin{pmatrix} 5 & 6 & 3 & 0 \\ 4 & 7 & 4 & 0 \\ 1 & 4 & 4 & 2 \\ 0 & 1 & 2 & 3 \end{pmatrix}$$

of the planar network in Figure 1 is the matrix of Example 1.1. Thus, M is totally nonnegative, by Lindström's Lemma. $\square$

1.3 Cell decomposition

Our main concern in this section is to consider the possible patterns of zeros that can occur as the values of the minors of a totally nonnegative matrix. The following

example shows that one cannot choose a subset of minors arbitrarily and hope to find a totally nonnegative matrix for which the chosen subset is precisely the subset of minors with value zero.

Example 1.9. There is no 2×2 totally nonnegative matrix $\begin{pmatrix} a & b \\ c & d \end{pmatrix}$ with $d = 0$, but the other four minors nonzero. For, suppose that $\begin{pmatrix} a & b \\ c & d \end{pmatrix}$ is TNN and $d = 0$. Then $a, b, c \geq 0$ and also $ad - bc \geq 0$. Thus, $-bc \geq 0$ and hence $bc = 0$ so that $b = 0$ or $c = 0$. $\square$

Let $\mathcal{M}_{m,p}^{\text{tnn}}$ be the set of totally nonnegative $m \times p$ real matrices. Let Z be a subset of minors. The cell S_Z° is the set of matrices in $\mathcal{M}_{m,p}^{\text{tnn}}$ for which the minors in Z are zero (and those not in Z are nonzero). Some cells may be empty. The space $\mathcal{M}_{m,p}^{\text{tnn}}$ is partitioned by the nonempty cells.

Exercise 1.10. Show that there are 14 nonempty cells in $\mathcal{M}_2^{\text{tnn}}$. $\square$

The question is then to describe the patterns of minors that represent nonempty cells in the space of totally nonnegative matrices. In [34], Postnikov defines *Le-diagrams* to solve this problem. An $m \times p$ array with entries either 0 or 1 is said to be a *Le-diagram* if it satisfies the following rule: if there is a 0 in a given square then either each square to the left is also filled with 0 or each square above is also filled with 0.

Here are an example and a non-example of a Le-diagram on a 5×5 array.

1	1	0	1	0
0	0	0	1	0
1	1	1	1	0
0	0	0	1	0

1	1	0	1	0
0	0	1	0	1
1	1	1	0	1
0	0	1	1	1
1	1	1	1	1

Theorem 1.11. (Postnikov) *There is a bijection between Le-diagrams on an $m \times p$ array and nonempty cells S_Z° in $\mathcal{M}_{m,p}^{\text{tnn}}$.*

In fact, Postnikov proves this theorem for the totally nonnegative grassmannian, and we are interpreting the result on the big cell, which is the space of totally nonnegative matrices.

In view of Exercise 1.10, there should be 14 2×2 Le-diagrams.

Exercise 1.12. The 16 possible fillings of a 2×2 array with either 0 or 1 are shown in Figure 2. Identify the two non-Le-diagrams. $\square$

In [34], Postnikov describes an algorithm that starts with a Le-diagram and produces a planar network from which one generates a totally nonnegative matrix which defines a nonempty cell in the space of totally nonnegative matrices. The procedure to produce the planar network is as follows. In each 1 box of the Le-diagram, place a black dot. From each black dot draw a hook which goes to the right end of the diagram and the bottom of the diagram. Label the right ends of the horizontal part of the hooks as the sources of a planar network, numbered from

Figure 2: 2×2 Le-diagrams

top to bottom, and label the bottom ends of the vertical part of the hooks as the sinks, numbered from left to right. Then consider the resulting graph to be directed by allowing movement from right to left along horizontal lines and top to bottom along vertical lines. By Lindström's Lemma (see Theorem 1.6) the path matrix of this planar network is a totally nonnegative matrix, and so the pattern of its zero minors produces a nonempty cell in the space of totally nonnegative matrices. The above procedure that associates to any Le-diagram a nonempty cell provides a bijection between the set of $m \times p$ Le-diagrams and nonempty cells in the space of totally nonnegative $m \times p$ matrices (see Theorem 1.11). We illustrate Postnikov's procedure with an example.

Example 1.13. The Le-diagram

1	0	1
0	0	1
1	1	1

produces the following planar network

where s_1 , s_2 and s_3 are the sources and t_1 , t_2 and t_3 are the sinks. The path matrix of this planar network is

$$\begin{pmatrix} 2 & 1 & 1 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{pmatrix}.$$

The minors that vanish on this matrix are:

$$[1, 2|2, 3], [1, 3|2, 3], [2, 3|2, 3], [2, 3|1, 3], [2, 3|1, 2], [1, 2, 3|1, 2, 3].$$

The cell associated to this family of minors is nonempty and this is the nonempty cell associated to the Le-diagram above. $\square$

In fact, by allowing suitable weights on the edges of the above planar network, one can obtain all of the matrices in this cell as weighted path matrices of the planar network.

2 Quantum matrices

We denote by $R := O_q(\mathcal{M}_{m,p}(\mathbb{C}))$ the standard quantisation of the ring of regular functions on $m \times p$ matrices with entries in $\mathbb{C}$; the algebra R is the $\mathbb{C}$ -algebra generated by the $m \times p$ indeterminates $X_{i,\alpha}$, for $1 \leq i \leq m$ and $1 \leq \alpha \leq p$, subject to the following relations:

$$\begin{aligned} X_{i,\beta}X_{i,\alpha} &= q^{-1}X_{i,\alpha}X_{i,\beta}, & (\alpha < \beta); \\ X_{j,\alpha}X_{i,\alpha} &= q^{-1}X_{i,\alpha}X_{j,\alpha}, & (i < j); \\ X_{j,\beta}X_{i,\alpha} &= X_{i,\alpha}X_{j,\beta}, & (i < j, \alpha > \beta); \\ X_{j,\beta}X_{i,\alpha} &= X_{i,\alpha}X_{j,\beta} - (q - q^{-1})X_{i,\beta}X_{j,\alpha}, & (i < j, \alpha < \beta). \end{aligned}$$

It is well known that R can be presented as an iterated Ore extension over $\mathbb{C}$, with the generators $X_{i,\alpha}$ adjoined in lexicographic order. Thus, the ring R is a noetherian domain; its skew-field of fractions is denoted by F or $F(R)$. In the case that q is not a root of unity, it follows from [19, Theorem 3.2] that all prime ideals of R are completely prime. In this survey, we will assume that q is not a root of unity.

Let K be a $\mathbb{C}$ -algebra and $M = (x_{i,\alpha}) \in \mathcal{M}_{m,p}(K)$. If $I \subseteq \llbracket 1, m \rrbracket$ and $\Lambda \subseteq \llbracket 1, p \rrbracket$ with $|I| = |\Lambda| = t \geq 1$, then we denote by $[I|\Lambda]_q(M)$ the corresponding *quantum*

minor of M . This is the element of K defined by:

$$[I|\Lambda]_q(M) = [i_1, \dots, i_k | \alpha_1, \dots, \alpha_k]_q := \sum_{\sigma \in S_k} (-q)^{l(\sigma)} x_{i_1, \alpha_{\sigma(1)}} \cdots x_{i_k, \alpha_{\sigma(k)}},$$

where $I = \{i_1, \dots, i_k\}$, $\Lambda = \{\alpha_1, \dots, \alpha_k\}$ and $l(\sigma)$ denotes the length of the k -permutation σ . Also, it is convenient to allow the empty minor: $[\emptyset|\emptyset]_q(M) := 1 \in K$. Whenever we write a quantum minor in the form $[i_1, \dots, i_k | \alpha_1, \dots, \alpha_k]_q$, we tacitly assume that the row and column indices are listed in ascending order, that is, $i_1 < \dots < i_l$ and $\alpha_1 < \dots < \alpha_l$.

The *quantum minors* in R are the quantum minors of the matrix $(X_{i,\alpha}) \in \mathcal{M}_{m,p}(R)$. To simplify the notation, we denote by $[I|\Lambda]_q$ the quantum minor of R associated to the row-index set I and the column-index set Λ .

It is easy to check that the torus $\mathcal{H} := (\mathbb{C}^\times)^{m+p}$ acts on R by $\mathbb{C}$ -algebra automorphisms via:

$$(a_1, \dots, a_m, b_1, \dots, b_p).X_{i,\alpha} = a_i b_\alpha X_{i,\alpha} \quad \text{for all} \quad (i, \alpha) \in \llbracket 1, m \rrbracket \times \llbracket 1, p \rrbracket.$$

We refer to this action as the *standard action* of $(\mathbb{C}^\times)^{m+p}$ on $O_q(\mathcal{M}_{m,p}(\mathbb{C}))$. Recall that an $\mathcal{H}$ -prime ideal of R is a proper $\mathcal{H}$ -invariant ideal P such that whenever P contains a product IJ of two $\mathcal{H}$ -invariant ideals, it must contain either I or J . As q is not a root of unity, it follows from [20, 5.7] that there are only finitely many $\mathcal{H}$ -primes in R and that every $\mathcal{H}$ -prime is completely prime. Hence, the $\mathcal{H}$ -prime ideals of R coincide with the $\mathcal{H}$ -invariant primes. We denote by $\mathcal{H} - \text{Spec}(R)$ the set of $\mathcal{H}$ -primes of R .

The aim is to parameterise/study the $\mathcal{H}$ -prime ideals in quantum matrices.

Example 2.1. The algebra of 2×2 quantum matrices may be presented as

$$\mathcal{O}_q(\mathcal{M}_2(\mathbb{C})) := \mathbb{C} \begin{bmatrix} a & b \\ c & d \end{bmatrix}$$

with relations

$$\begin{aligned} ab &= qba & ac &= qca & bc &= cb \\ bd &= qdb & cd &= qdc & ad - da &= (q - q^{-1})bc. \end{aligned}$$

The *quantum determinant* is $D_q := [12|12]_q = ad - qbc$.

Let P be a prime ideal that contains d . Then

$$(q - q^{-1})bc = ad - da \in P$$

and, as $0 \neq (q - q^{-1}) \in \mathbb{C}$ and P is completely prime, we deduce that either $b \in P$ or $c \in P$. Thus, there is no prime ideal in $\mathcal{O}_q(\mathcal{M}_2(\mathbb{C}))$ such that d is the only quantum minor that is in P . $\square$

You should notice the analogy with the corresponding result in the space of 2×2 totally nonnegative matrices: the cell corresponding to d being the only vanishing minor is empty (see Example 1.9).

2.1 $\mathcal{H}$ -primes and Cauchon diagrams.

In [8], Cauchon showed that his theory of deleting derivations can be applied to the iterated Ore extension R . As a consequence, he was able to parametrise the set $\mathcal{H}\text{-Spec}(R)$ in terms of combinatorial objects called *Cauchon diagrams*.

Definition 2.2. [8] An $m \times p$ *Cauchon diagram* C is simply an $m \times p$ grid consisting of mp squares in which certain squares are coloured black. We require that the collection of black squares have the following property: If a square is black, then either every square strictly to its left is black or every square strictly above it is black.

We denote by $\mathcal{C}_{m,p}$ the set of $m \times p$ Cauchon diagrams.

Note that we will often identify an $m \times p$ Cauchon diagram with the set of coordinates of its black boxes. Indeed, if $C \in \mathcal{C}_{m,p}$ and $(i, \alpha) \in \llbracket 1, m \rrbracket \times \llbracket 1, p \rrbracket$, we will say that $(i, \alpha) \in C$ if the box in row i and column α of C is black.

Figure 3: An example of a 4×5 Cauchon diagram

Recall [8, Corollaire 3.2.1] that Cauchon has constructed (using the deleting derivations algorithm) a bijection between $\mathcal{H}\text{-Spec}(O_q(\mathcal{M}_{m,p}(\mathbb{C})))$ and the collection $\mathcal{C}_{m,p}$. As a consequence, Cauchon [8] was able to give a formula for the size of $\mathcal{H}\text{-Spec}(O_q(\mathcal{M}_{m,p}(\mathbb{C})))$. This formula was later re-written by Goodearl and McCammond (see [27]) in terms of Stirling numbers of second kind and poly-Bernoulli numbers as defined by Arakawa and Kaneko (see [1, 22]).

Notice that the definitions of Le-diagrams and Cauchon diagrams are the same! Thus, the nonempty cells in totally nonnegative matrices and the $\mathcal{H}$ -prime ideals in quantum matrices are parameterised by the same combinatorial objects. Much more is true, as we will now see.

For example, $\mathcal{O}_q(\mathcal{M}_2(\mathbb{C}))$ has 14 $\mathcal{H}$ -prime ideals, as there are 14 Cauchon/Le-diagrams. It is relatively easy to identify these $\mathcal{H}$ -primes. The following are the $\mathcal{H}$ -prime ideals of $\mathcal{O}_q(\mathcal{M}_2(\mathbb{C}))$.

To interpret this picture, note that, for example, $\begin{pmatrix} a & b \\ c & 0 \end{pmatrix}$ denotes the ideal generated by a, b and c .

It is easy to check that 13 of the ideals are prime. For example, let P be the ideal generated by b and d . Then $\mathcal{O}_q(\mathcal{M}_2(\mathbb{C}))/P \cong \mathbb{C}[a, c]$ and $\mathbb{C}[a, c]$ is an iterated Ore extension of $\mathbb{C}$ and so a domain. The only problem is to show that the determinant generates a prime ideal. This was originally proved by Jordan, and, independently, by Levasseur and Stafford. A general result that includes this as a special case is [16, Theorem 2.5].

In fact, in the case that the parameter q is transcendental over $\mathbb{Q}$, the first author, [26] has shown that all $\mathcal{H}$ -prime ideals are generated by the quantum minors that they contain. In [15], this result is extended by replacing $\mathbb{C}$ by any field of characteristic zero (still retaining the condition that q is transcendental over $\mathbb{Q}$). The transcendental restriction is technical: at the moment, a certain ideal is only known to be prime with this restriction. It is expected that the result will remain true when q is merely restricted to be not a root of unity.

If you did Exercise 1.10 then you will notice that the sets of all quantum minors that define $\mathcal{H}$ -prime ideals in $\mathcal{O}_q(\mathcal{M}_2(\mathbb{C}))$ are exactly the quantum versions of the sets of vanishing minors for nonempty cells in the space of 2×2 totally nonnegative matrices. This coincidence also occurs in the general case and an explanation of this coincidence is obtained in [14, 15]. However, in order to explain the coincidence, we need to introduce a third setting, that of Poisson matrices, and this is done in the next section.

3 Poisson matrix varieties and their $\mathcal{H}$ -orbits of symplectic leaves

In this section, we study the standard Poisson structure of the coordinate ring $\mathcal{O}(\mathcal{M}_{m,p}(\mathbb{C}))$ coming from the commutators of $\mathcal{O}_q(\mathcal{M}_{m,p}(\mathbb{C}))$. Recall that a *Poisson algebra* (over $\mathbb{C}$) is a commutative $\mathbb{C}$ -algebra A equipped with a Lie bracket $\{-, -\}$

which is a derivation (for the associative multiplication) in each variable. The derivations $\{a, -\}$ on A are called *Hamiltonian derivations*. When A is the algebra of complex-valued C^∞ functions on a smooth affine variety V , one can use Hamiltonian derivations in order to define Hamiltonian paths in V . A smooth path $\gamma : [0, 1] \rightarrow V$ is a *Hamiltonian path in V* if there exists $H \in C^\infty(V)$ such that for all $f \in \mathcal{C}^\infty(V)$:

$$\frac{d}{dt}(f \circ \gamma)(t) = \{H, f\} \circ \gamma(t), \quad (1)$$

for all $0 < t < 1$. In other words, Hamiltonian paths are the integral curves (or flows) of the Hamiltonian vector fields induced by the Poisson bracket. It is easy to check that the relation “connected by a piecewise Hamiltonian path” is an equivalence relation. The equivalence classes of this relation are called the *symplectic leaves* of V ; they form a partition of V .

3.1 The Poisson algebra $\mathcal{O}(\mathcal{M}_{m,p}(\mathbb{C}))$

Denote by $\mathcal{O}(\mathcal{M}_{m,p}(\mathbb{C}))$ the coordinate ring of the variety $\mathcal{M}_{m,p}(\mathbb{C})$; note that $\mathcal{O}(\mathcal{M}_{m,p}(\mathbb{C}))$ is a (commutative) polynomial algebra in mp indeterminates $Y_{i,\alpha}$ with $1 \leq i \leq m$ and $1 \leq \alpha \leq p$.

The variety $\mathcal{M}_{m,p}(\mathbb{C})$ is a Poisson variety: there is a unique Poisson bracket on the coordinate ring $\mathcal{O}(\mathcal{M}_{m,p}(\mathbb{C}))$ determined by the following data. For all $(i, \alpha) < (k, \gamma)$, we set:

$$\{Y_{i,\alpha}, Y_{k,\gamma}\} = \begin{cases} Y_{i,\alpha}Y_{k,\gamma} & \text{if } i = k \text{ and } \alpha < \gamma \\ Y_{i,\alpha}Y_{k,\gamma} & \text{if } i < k \text{ and } \alpha = \gamma \\ 0 & \text{if } i < k \text{ and } \alpha > \gamma \\ 2Y_{i,\gamma}Y_{k,\alpha} & \text{if } i < k \text{ and } \alpha < \gamma. \end{cases}$$

This is the standard Poisson structure on the affine variety $\mathcal{M}_{m,p}(\mathbb{C})$ (cf. [4, §1.5]); the Poisson algebra structure on $\mathcal{O}(\mathcal{M}_{m,p}(\mathbb{C}))$ is the semiclassical limit of the non-commutative algebras $\mathcal{O}_q(\mathcal{M}_{m,p}(\mathbb{C}))$. Indeed one can easily check that

$$\{Y_{i,\alpha}, Y_{k,\gamma}\} = \frac{[X_{i,\alpha}, X_{k,\gamma}]}{q-1} \Big|_{q=1}.$$

In particular, the Poisson bracket on $\mathcal{O}(\mathcal{M}_2(\mathbb{C})) = \mathbb{C} \begin{bmatrix} a & b \\ c & d \end{bmatrix}$ is defined by:

$$\begin{aligned} \{a, b\} &= ab & \{a, c\} &= ac & \{b, c\} &= 0 \\ \{b, d\} &= bd & \{c, d\} &= cd & \{a, d\} &= 2bc. \end{aligned}$$

Note that the Poisson bracket on $\mathcal{O}(\mathcal{M}_{m,p}(\mathbb{C}))$ extends uniquely to a Poisson bracket on $\mathcal{C}^\infty(\mathcal{M}_{m,p}(\mathbb{C}))$, so that $\mathcal{M}_{m,p}(\mathbb{C})$ can be viewed as a Poisson manifold. Hence, $\mathcal{M}_{m,p}(\mathbb{C})$ can be decomposed as the disjoint union of its symplectic leaves. Before studying symplectic leaves in $\mathcal{M}_{m,p}(\mathbb{C})$, let us explicitly describe the Poisson bracket on $\mathcal{C}^\infty(\mathcal{M}_2(\mathbb{C}))$. For all $f, g \in \mathcal{C}^\infty(\mathcal{M}_2(\mathbb{C}))$, one has:

$$\begin{aligned} \{f, g\} &= \\ & ab \left(\frac{\partial f}{\partial a} \cdot \frac{\partial g}{\partial b} - \frac{\partial f}{\partial b} \cdot \frac{\partial g}{\partial a} \right) + ac \left(\frac{\partial f}{\partial a} \cdot \frac{\partial g}{\partial c} - \frac{\partial f}{\partial c} \cdot \frac{\partial g}{\partial a} \right) + bd \left(\frac{\partial f}{\partial b} \cdot \frac{\partial g}{\partial d} - \frac{\partial f}{\partial d} \cdot \frac{\partial g}{\partial b} \right) \\ & + cd \left(\frac{\partial f}{\partial c} \cdot \frac{\partial g}{\partial d} - \frac{\partial f}{\partial d} \cdot \frac{\partial g}{\partial c} \right) + 2bc \left(\frac{\partial f}{\partial a} \cdot \frac{\partial g}{\partial d} - \frac{\partial f}{\partial d} \cdot \frac{\partial g}{\partial a} \right). \end{aligned}$$

We finish this section by proving an analogue of Examples 1.9 and 2.1 in the Poisson setting.

Proposition 3.1. *Let $\mathcal{L}$ be a symplectic leaf such that $d(M) = 0$ for all $M \in \mathcal{L}$. Then, either $b(M) = 0$ for all $M \in \mathcal{L}$ or $c(M) = 0$ for all $M \in \mathcal{L}$.*

Proof. Let $N = \begin{pmatrix} \alpha & \beta \\ \gamma & 0 \end{pmatrix} \in \mathcal{L}$. We first prove that $\beta\gamma = 0$. We distinguish between two cases.

First assume that $\alpha = 0$. Then we claim that the path defined by $\begin{pmatrix} 0 & \beta \\ \gamma & 2\beta\gamma t \end{pmatrix}$ is a flow of the Hamiltonian vector field associated to $\{a, -\}$, and so a Hamiltonian path starting at N . As $N \in \mathcal{L}$, every point of this Hamiltonian path should be in $\mathcal{L}$. In particular, we get that $\begin{pmatrix} 0 & \beta \\ \gamma & 2\beta\gamma \end{pmatrix} \in \mathcal{L}$. As $d(M) = 0$ for all $M \in \mathcal{L}$, we get $\beta\gamma = 0$ as desired.

Next assume that $\alpha \neq 0$. Then we claim that $\begin{pmatrix} \alpha & \beta e^{\alpha t} \\ \gamma e^{\alpha t} & \frac{\beta\gamma}{\alpha} e^{2\alpha t} \end{pmatrix}$ is a flow of the Hamiltonian vector field associated to $\{a, -\}$, and so a Hamiltonian path starting at N . As in the previous case this implies $\beta\gamma = 0$ as desired.

Hence, the leaf $\mathcal{L}$ contains a point N of the form

$$N = \begin{pmatrix} \alpha & \beta \\ 0 & 0 \end{pmatrix} \text{ or } N = \begin{pmatrix} \alpha & 0 \\ \gamma & 0 \end{pmatrix}.$$

We prove in the first case that $c(M) = 0$ for all $M \in \mathcal{L}$. It is enough to prove that if $\gamma : [0, 1] \rightarrow \mathcal{M}_2(\mathbb{C})$ is a Hamiltonian path such that $d(\gamma(t)) = 0$ for all $t \in [0, 1]$ and $c(\gamma(0)) = 0$, then $c(\gamma(t)) = 0$ for all $t \in [0, 1]$. Let γ be such a Hamiltonian path. For all $t \in [0, 1]$, we set $\gamma(t) = \begin{pmatrix} \gamma_1(t) & \gamma_2(t) \\ \gamma_3(t) & 0 \end{pmatrix}$. It follows from (1) that

$$\frac{d}{dt}(c \circ \gamma)(t) = \{H, c\} \circ \gamma(t).$$

Hence as $\gamma_4(t) = 0$ for all t , we get

$$\gamma_3'(t) = \gamma_1(t)\gamma_3(t)\frac{\partial H}{\partial a}(\gamma(t)).$$

Set $\alpha(t) := \gamma_1(t)\frac{\partial H}{\partial a}(\gamma(t))$. Then

$$\gamma_3'(t) = \alpha(t)\gamma_3(t).$$

Hence we have

$$\gamma_3(t) = C \exp(\Lambda(t))$$

for all $t \in [0, 1]$, where $C \in \mathbb{C}$ and Λ is a primitive of $\alpha \in C^\infty([0, 1])$. As $\gamma_3(0) = 0$ we must have $C = 0$, so that $\gamma_3(t) = 0$ for all t , as desired. $\square$

3.2 $\mathcal{H}$ -orbits of symplectic leaves in $\mathcal{M}_{m,p}(\mathbb{C})$

Notice that the torus $\mathcal{H} := (\mathbb{C}^\times)^{m+p}$ acts on $\mathcal{O}(\mathcal{M}_{m,p}(\mathbb{C}))$ by Poisson automorphisms via:

$$(a_1, \dots, a_m, b_1, \dots, b_p).Y_{i,\alpha} = a_i b_\alpha Y_{i,\alpha} \quad \text{for all } (i, \alpha) \in \llbracket 1, m \rrbracket \times \llbracket 1, p \rrbracket.$$

Note that $\mathcal{H}$ is acting rationally on $\mathcal{O}(\mathcal{M}_{m,p}(\mathbb{C}))$.

At the geometric level, this action of the algebraic torus $\mathcal{H}$ comes from the left action of $\mathcal{H}$ on $\mathcal{M}_{m,p}(\mathbb{C})$ by Poisson isomorphisms via:

$$(a_1, \dots, a_m, b_1, \dots, b_p).M := \text{diag}(a_1, \dots, a_m)^{-1} \cdot M \cdot \text{diag}(b_1, \dots, b_p)^{-1}.$$

This action of $\mathcal{H}$ on $\mathcal{M}_{m,p}(\mathbb{C})$ induces an action of $\mathcal{H}$ on the set $\text{Symp}(\mathcal{M}_{m,p}(\mathbb{C}))$ of symplectic leaves in $\mathcal{M}_{m,p}(\mathbb{C})$ (cf. [4, §0.1]). As in [4], we view the $\mathcal{H}$ -orbit of a symplectic leaf $\mathcal{L}$ as the set-theoretic union $\bigcup_{h \in \mathcal{H}} h.\mathcal{L} \subseteq \mathcal{M}_{m,p}(\mathbb{C})$, rather than as the family $\{h.\mathcal{L} \mid h \in \mathcal{H}\}$. We denote the set of such orbits by $\mathcal{H}\text{-Symp}(\mathcal{M}_{m,p}(\mathbb{C}))$.

As the symplectic leaves of $\mathcal{M}_{m,p}(\mathbb{C})$ form a partition of $\mathcal{M}_{m,p}(\mathbb{C})$, so too do the $\mathcal{H}$ -orbits of symplectic leaves.

Example 3.2. The symplectic leaf $\mathcal{L}$ containing $\begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix}$ is the set $\mathcal{E}$ of those 2×2 complex matrices $M = \begin{pmatrix} x & y \\ z & t \end{pmatrix}$ with $y - z = 0$, $xt - yz = 0$ and $y \neq 0$. In other words,

$$\mathcal{E} := \{M \in \mathcal{M}_2(\mathbb{C}) \mid \Delta(M) = 0, (b - c)(M) = 0 \text{ and } b(M) \neq 0\},$$

where a, b, c, d denote the canonical generators of the coordinate ring of $\mathcal{M}_2(\mathbb{C})$ and $\Delta := ad - bc$ is the determinant function. It easily follows from this that the $\mathcal{H}$ -orbit of symplectic leaves in $\mathcal{M}_2(\mathbb{C})$ that contains the point $\begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix}$ is the set of those 2×2 matrices M with $\Delta(M) = 0$ and $b(M).c(M) \neq 0$. Moreover the closure of this $\mathcal{H}$ -orbit coincides with the set of those 2×2 matrices M with $\Delta(M) = 0$. $\square$

The $\mathcal{H}$ -orbits of symplectic leaves in $\mathcal{M}_{m,p}(\mathbb{C})$ have been explicitly described by Brown, Goodearl and Yakimov in [4]. The following result was proved in [4, Theorems 3.9, 3.13, 4.2].

Theorem 3.3. *Set*

$$\mathcal{S} = \{w \in S_{m+p} \mid -p \leq w(i) - i \leq m \text{ for all } i = 1, 2, \dots, m+p\}.$$

1. *The $\mathcal{H}$ -orbits of symplectic leaves in $\mathcal{M}_{m,p}(\mathbb{C})$ are smooth irreducible locally closed subvarieties.*
2. *There is an explicit $1 : 1$ correspondence between $\mathcal{S}$ and $\mathcal{H}\text{-Symp}(\mathcal{M}_{m,p}(\mathbb{C}))$.*
3. *Each $\mathcal{H}$ -orbit is defined by some rank conditions.*

The rank conditions that define the $\mathcal{H}$ -orbits of symplectic leaves and their closures are explicit in [4]. The reader is referred to [4] for more details.

For $w \in \mathcal{S}$, we denote by $\mathcal{P}_w$ the $\mathcal{H}$ -orbit of symplectic leaves associated to the restricted permutation w .

Before going any further let us look at a special case. In the 2×2 case, the Theorem of Brown, Goodearl and Yakimov asserts that there is a $1 : 1$ correspondence between

$$\mathcal{S} = \{w \in S_4 \mid -2 \leq w(i) - i \leq 2 \text{ for all } i = 1, 2, 3, 4\}.$$

and $\mathcal{H}\text{-Sympl}(\mathcal{M}_2(\mathbb{C}))$. In other words, there is a bijection between the set of those permutations w in S_4 such that $w(1) \neq 4$ and $w(4) \neq 1$. One may be disappointed not to retrieve 2×2 Cauchon diagrams, but a direct inspection shows that there are exactly 14 such restricted permutations in the 2×2 case! This is not at all a coincidence as we will see in the following section.

To finish, let us mention that the set of all minors that vanish on the closure of the $\mathcal{H}$ -orbit of symplectic leaves associated to $w \in \mathcal{S}$ has been described in [14]. In order to describe this result, we need to introduce some notation.

Set $N = m + p$, and let $w_\circ^m$, $w_\circ^p$ and $w_\circ^N$ denote the longest elements in S_m , S_p and S_N , respectively, so that $w_\circ^r(i) = r + 1 - i$ for $i = 1, \dots, r$.

Definition 3.4. For $w \in \mathcal{S}$, define $\mathcal{M}(w)$ to be the set of minors $[I|\Lambda]$, with $I \subseteq \llbracket 1, m \rrbracket$ and $\Lambda \subseteq \llbracket 1, p \rrbracket$, that satisfy at least one of the following conditions.

1. $I \not\leq w_\circ^m w(L)$ for all $L \subseteq \llbracket 1, p \rrbracket \cap w^{-1}\llbracket 1, m \rrbracket$ such that $|L| = |I|$ and $L \leq \Lambda$.
2. $m + \Lambda \not\leq w w_\circ^N(L)$ for all $L \subseteq \llbracket 1, m \rrbracket \cap w_\circ^N w^{-1}\llbracket m + 1, N \rrbracket$ such that $|L| = |\Lambda|$ and $L \leq I$.
3. There exist $1 \leq r \leq s \leq p$ and $\Lambda' \subseteq \Lambda \cap \llbracket r, s \rrbracket$ such that $|\Lambda'| > |\llbracket r, s \rrbracket \setminus w^{-1}\llbracket m + r, m + s \rrbracket|$.
4. There exist $1 \leq r \leq s \leq m$ and $I' \subseteq I \cap \llbracket r, s \rrbracket$ such that $|I'| > |w_\circ^N \llbracket r, s \rrbracket \setminus w^{-1} w_\circ^m \llbracket r, s \rrbracket|$.

Example 3.5. For example, when $m = p = 3$ and $w = (2 \ 3 \ 5 \ 4)$, then $\mathcal{M}(w) = \{[1, 2|2, 3], [1, 3|2, 3], [2, 3|2, 3], [2, 3|1, 3], [2, 3|1, 2], [1, 2, 3|1, 2, 3]\}$. We observe that this family of minors defines a nonempty cell in $\mathcal{M}_3^{\text{tnn}}(\mathbb{R})$ by Example 1.9. $\square$

In [14], the following result was obtained thanks to previous results of [4] and [11].

Theorem 3.6. *Let $w \in \mathcal{S}$. The closure of the $\mathcal{H}$ -orbit $\mathcal{P}_w$ is given by:*

$$\overline{\mathcal{P}_w} = \{x \in \mathcal{M}_{m,p}(\mathbb{C}) \mid [I|J](x) = 0 \text{ for all } [I|J] \in \mathcal{M}(w)\}.$$

Moreover, the minor $[I|J]$ vanishes on $\overline{\mathcal{P}_w}$ if and only if $[I|J] \in \mathcal{M}(w)$.

4 From Cauchon diagrams to restricted permutations and back, via pipe dreams

In the previous section, we have seen that the torus-orbits of symplectic leaves in $\mathcal{M}_{m,p}(\mathbb{C})$ are parameterised by the restricted permutations in S_{m+p} given by

$$\mathcal{S} = \{w \in S_{m+p} \mid -p \leq w(i) - i \leq m \text{ for all } i = 1, 2, \dots, m + p\}.$$

In the 2×2 case, this subposet of the Bruhat poset of S_4 is

$$\mathcal{S} = \{w \in S_4 \mid -2 \leq w(i) - i \leq 2 \text{ for all } i = 1, 2, 3, 4\}.$$

and is shown below.

Inspection of this poset reveals that it is isomorphic to the poset of the $\mathcal{H}$ -prime ideals of $\mathcal{O}_q(\mathcal{M}_2(\mathbb{C}))$ displayed in Section 2; and so to a similar poset of the Cauchon diagrams corresponding to the $\mathcal{H}$ -prime ideals.

More generally, it is known that the numbers of $\mathcal{H}$ -primes in $\mathcal{O}_q(\mathcal{M}_{m,p}(\mathbb{C}))$ (and so the number of $m \times p$ Cauchon diagrams) is equal to $|\mathcal{S}|$ (see [28]). This is no coincidence, and the connection between the two posets can be illuminated by using *Pipe Dreams*.

The procedure to produce a restricted permutation from a Cauchon diagram goes as follows. Given a Cauchon diagram, replace each black box by a cross, and each white box by an elbow joint, that is:

For example, the Cauchon diagram

produces the pipe dream

We obtain a permutation σ from the pipe dream in the following way. To calculate $\sigma(i)$, locate the i either on the right hand side or the bottom of the pipe dream and trace through the pipe dream to find the number $\sigma(i)$ that is at the end of the pipe starting at i . In the example displayed, we find that $\sigma = 135246$ (in one-line notation).

It is easy to check that this produces a restricted permutation of the required type by using the observation that as you move along a pipe from source to image, you can only move upwards and leftwards; so, for example, in any 3×3 example $\sigma(2)$ is at most 5 (the number directly above 2).

This procedure provides an explicit bijection between the set of $m \times p$ Cauchon diagrams and the poset $\mathcal{S}$ (see [34, 9]).

5 The Unifying Theory

In the previous sections we have seen that the nonempty cells in $\mathcal{M}_{m,p}^{\text{tnn}}$, the torus-invariant prime ideals in $O_q(\mathcal{M}_{m,p}(\mathbb{C}))$ and the closure of the $\mathcal{H}$ -orbits of symplectic leaves are all parametrised by $m \times p$ Cauchon diagrams. This suggests that there might be a connection between these objects. Going a step further, all these objects are characterised by certain families of (quantum) minors.

First, totally nonnegative cells are defined by the vanishing of families of minors. Some of the TNN cells are empty. So it is natural to introduce the following definition. A family of minors is *admissible* if the corresponding TNN cell is nonempty. The obvious question to ask is:

Question: what are the admissible families of minors?

Next, in the quantum case, $\mathcal{H}$ -primes of $O_q(\mathcal{M}_{m,p}(\mathbb{C}))$ are generated by quantum minors when we assume that q is transcendental over $\mathbb{Q}$. The obvious question in this setting is:

Question: which families of quantum minors generate $\mathcal{H}$ -invariant prime ideals?

Finally, it follows from the work of Brown, Goodearl and Yakimov that the closure of the $\mathcal{H}$ -orbits of symplectic leaves in $\mathcal{M}_{m,p}(\mathbb{C})$ are algebraic, and are defined by rank conditions. In other words, they are defined by the vanishing of some families of minors. The obvious question in this context is:

Question: which families of minors?

At first, we may be tempted to propose the following conjecture. Let Z_q be a family of quantum minors, and Z be the corresponding family of minors. Then $\langle Z_q \rangle$ is a $\mathcal{H}$ -prime ideal if and only if the cell S_Z^0 is nonempty.

Stated like this, this conjecture is wrong. The problem here is that distinct families of minors may generate the same $\mathcal{H}$ -invariant prime ideal. For instance, the ideal generated by a and b in $\mathcal{O}_q(\mathcal{M}_2(\mathbb{C}))$ coincides with the ideal generated by a , b and the quantum determinant $[1, 2|1, 2]_q$; moreover this ideal is an $\mathcal{H}$ -invariant prime ideal. So we need to be a bit more precise in order to get a correct statement. It turns out that the right thing to do is to compare the admissible families of minors first with the set of all minors that vanish on the closure of a torus-orbit of symplectic leaves in $\mathcal{M}_{m,p}(\mathbb{C})$, and second with the set of all quantum minors that belong to a torus-invariant prime ideal in $\mathcal{O}_q(\mathcal{M}_{m,p}(\mathbb{C}))$.

5.1 An algorithm to rule them all

In [6, 7, 8], Cauchon developed and used an algorithm, called the *deleting derivations algorithm* in order to study the $\mathcal{H}$ -invariant prime ideals in $\mathcal{O}_q(\mathcal{M}_{m,p}(\mathbb{C}))$. Roughly speaking, in the 2×2 case, this algorithm consists in the following change of variable:

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix} \longrightarrow \begin{pmatrix} a - bd^{-1}c & b \\ c & d \end{pmatrix}.$$

Let us now give a precise definition of the deleting derivations algorithm.

If $M = (x_{i,\alpha}) \in \mathcal{M}_{m,p}(K)$, then we set

$$g_{j,\beta}(M) = (x'_{i,\alpha}) \in \mathcal{M}_{m,p}(K),$$

where

$$x'_{i,\alpha} := \begin{cases} x_{i,\alpha} - x_{i,\beta}x_{j,\beta}^{-1}x_{j,\alpha} & \text{if } x_{j,\beta} \neq 0, i < j \text{ and } \alpha < \beta \\ x_{i,\alpha} & \text{otherwise.} \end{cases}$$

We set $M^{(j,\beta)} := g_{j,\beta} \circ \cdots \circ g_{m,p-1} \circ g_{m,p}(M)$ where the indices are taken in lexicographic order.

The matrix $M^{(1,1)}$ is called the matrix obtained from M at the end of the deleting derivations algorithm.

The deleting derivations algorithm has an inverse that is called the *restoration algorithm*. It was originally developed in [24] to study $\mathcal{H}$ -primes in quantum matrices. Roughly speaking, in the 2×2 case, the restoration algorithm consists of making the following change of variable:

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix} \longrightarrow \begin{pmatrix} a + bd^{-1}c & b \\ c & d \end{pmatrix}.$$

Let us now give a precise definition of the restoration algorithm.

If $M = (x_{i,\alpha}) \in \mathcal{M}_{m,p}(K)$, then we set

$$f_{j,\beta}(M) = (x'_{i,\alpha}) \in \mathcal{M}_{m,p}(K),$$

where

$$x'_{i,\alpha} := \begin{cases} x_{i,\alpha} + x_{i,\beta}x_{j,\beta}^{-1}x_{j,\alpha} & \text{if } x_{j,\beta} \neq 0, i < j \text{ and } \alpha < \beta \\ x_{i,\alpha} & \text{otherwise.} \end{cases}$$

We set $M^{(j,\beta)} := f_{j,\beta} \circ \cdots \circ f_{1,2} \circ f_{1,1}(M)$ where the indices are taken in the reverse of the lexicographic order.

The matrix $M^{(m,p)}$ is called the matrix obtained from M at the end of the restoration algorithm.

Example 5.1. Set $M = \begin{pmatrix} 1 & -1 & 1 \\ 0 & 2 & 1 \\ 1 & 1 & 1 \end{pmatrix}$. Then, applying the restoration algorithm to M , we get successively:

$$M^{(2,2)} = M^{(2,1)} = M^{(1,3)} = M^{(1,2)} = M^{(1,1)} = M,$$

$$M^{(3,1)} = M^{(2,3)} = \begin{pmatrix} 1 & 1 & 1 \\ 0 & 2 & 1 \\ 1 & 1 & 1 \end{pmatrix}, \quad M^{(3,2)} = \begin{pmatrix} 2 & 1 & 1 \\ 2 & 2 & 1 \\ 1 & 1 & 1 \end{pmatrix}$$

and

$$M^{(3,3)} = \begin{pmatrix} 3 & 2 & 1 \\ 3 & 3 & 1 \\ 1 & 1 & 1 \end{pmatrix}.$$

which is the matrix obtained from M at the end of the restoration algorithm. $\square$

5.2 The restoration algorithm and TNN matrices

It is easy to see that the matrix $M^{(3,3)}$ obtained from M by the restoration algorithm in Example 5.1 is not TNN. In fact, the only minor that is negative is $[1, 2|2, 3](M^{(3,3)})$. The reason for this failure to be TNN is that the starting matrix M has a negative entry. Moreover one can check by following the steps of the restoration algorithm that $[1, 2|2, 3](M^{(3,3)}) = m_{1,2}m_{2,3}$. In general, one can express the (quantum) minors of $M^{(j,\beta)^+}$ in terms of the (quantum) minors of $M^{(j,\beta)}$ (see [14, 15]). As a consequence, one is able to prove the following result that gives a necessary and sufficient condition for a real matrix to be TNN.

Theorem 5.2. [14]

1. *If the entries of M are nonnegative and its zeros form a Cauchon diagram, then the matrix $M^{(m,p)}$ obtained from M at the end of the restoration algorithm is TNN.*
2. *Let M be a matrix with real entries. We can apply the deleting derivations algorithm to M . Let N denote the matrix obtained at the end of the deleting derivations algorithm. Then M is TNN if and only if the matrix N is nonnegative and its zeros form a Cauchon diagram. (That is, the zeros of N correspond to the black boxes of a Cauchon diagram.)*

Exercise 5.3. Use the deleting derivations algorithm to test whether the following matrices are TNN:

$$M_1 = \begin{pmatrix} 11 & 7 & 4 & 1 \\ 7 & 5 & 3 & 1 \\ 4 & 3 & 2 & 1 \\ 1 & 1 & 1 & 1 \end{pmatrix} \text{ and } M_2 = \begin{pmatrix} 7 & 5 & 4 & 1 \\ 6 & 5 & 3 & 1 \\ 4 & 3 & 2 & 1 \\ 1 & 1 & 1 & 1 \end{pmatrix}.$$

5.3 Main result

Let C be an $m \times p$ Cauchon diagram and $T = (t_{i,\alpha})$ be a matrix with entries in a skew-field K . Assume that $t_{i,\alpha} = 0$ if and only if (i, α) is a black box of C . Set

$$T_C := f_{m,p} \circ \cdots \circ f_{1,2} \circ f_{1,1}(T),$$

so that T_C is the matrix obtained from T by the restoration algorithm.

Example 5.4. Let $m = p = 3$ and consider the Cauchon diagram

Then

$$T = \begin{pmatrix} t_{1,1} & 0 & t_{1,3} \\ 0 & 0 & t_{2,3} \\ t_{3,1} & t_{3,2} & t_{3,3} \end{pmatrix}$$

and $T^{(j,\beta)} := f_{j,\beta} \circ \cdots \circ f_{1,1}(T)$.

Then we have

$$T^{(3,2)} = T^{(3,1)} = T^{(2,3)} = T^{(2,2)} = T^{(2,1)} = T^{(1,3)} = T^{(1,2)} = T$$

and

$$T_C = T^{(3,3)} = \begin{pmatrix} t_{1,1} + t_{1,3}t_{3,3}^{-1}t_{3,1} & t_{1,3}t_{3,3}^{-1}t_{3,2} & t_{1,3} \\ t_{2,3}t_{3,3}^{-1}t_{3,1} & t_{2,3}t_{3,3}^{-1}t_{3,2} & t_{2,3} \\ t_{3,1} & t_{3,2} & t_{3,3} \end{pmatrix}.$$

□

The above construction can be applied in a variety of situations. In particular, we have the following.

- If $K = \mathbb{R}$ and T is nonnegative, then T_C is TNN.
- If the nonzero entries of T commute and are algebraically independent, and if $K = \mathbb{C}(t_{ij})$, then the minors of T_C that are equal to zero are exactly those that vanish on the closure of a given $\mathcal{H}$ -orbit of symplectic leaves. (See [14].)
- If the nonzero entries of T are the generators of a certain quantum affine space over $\mathbb{C}$ and K is the skew-field of fractions of this quantum affine space, then the quantum minors of T_C that are equal to zero are exactly those belonging to the unique $\mathcal{H}$ -prime in $O_q(\mathcal{M}_{m,p}(\mathbb{C}))$ associated to the Cauchon diagram C . (See [26] for more details.)

- The families of (quantum) minors we get depend only on C in these three cases. And if we start from the same Cauchon diagram in these three cases, then we get exactly the same families.

As a consequence, we get the following comparison result (see [14, 15]).

Theorem 5.5. *Let $\mathcal{F}$ be a family of minors in the coordinate ring of $\mathcal{M}_{m,p}(\mathbb{C})$, and let $\mathcal{F}_q$ be the corresponding family of quantum minors in $\mathcal{O}_q(\mathcal{M}_{m,p}(\mathbb{C}))$. Then the following are equivalent:*

1. *The totally nonnegative cell associated to $\mathcal{F}$ is nonempty.*
2. *$\mathcal{F}$ is the set of minors that vanish on the closure of a torus-orbit of symplectic leaves in $\mathcal{M}_{m,p}(\mathbb{C})$.*
3. *$\mathcal{F}_q$ is the set of quantum minors that belong to an $\mathcal{H}$ -prime in $\mathcal{O}_q(\mathcal{M}_{m,p}(\mathbb{C}))$.*

This result has several interesting consequences.

First, it easily follows from Theorem 5.5 that the TNN cells in $\mathcal{M}_{m,p}^{\text{tnn}}$ are the traces of the closure of $\mathcal{H}$ -orbits of symplectic leaves on $\mathcal{M}_{m,p}^{\text{tnn}}$.

Next, the sets of all minors that vanish on the closure of a torus-orbit of symplectic leaves in $\mathcal{M}_{m,p}(\mathbb{C})$ have been explicitly described in [14] (see also Theorem 3.6). So, as a consequence of the previous theorem, *the sets of minors that define nonempty totally nonnegative cells are explicitly described:* these are the families $\mathcal{M}(w)$ of Definition 3.4 for $w \in \mathcal{S}$. On the other hand, when the deformation parameter q is transcendental over the rationals, then the torus-invariant primes in $\mathcal{O}(\mathcal{M}_{m,p}(\mathbb{C}))$ are generated by quantum minors, and so we deduce from the above theorem *explicit generating sets of quantum minors for the torus-invariant prime ideals of $\mathcal{O}_q(\mathcal{M}_{m,p}(\mathbb{C}))$* . Recently and independently, Yakimov [38] also described explicit families of quantum minors that generate $\mathcal{H}$ -primes. However his families are smaller than ours and so are not adapted to the TNN world. The problem of deciding whether a given quantum minor belongs to the $\mathcal{H}$ -prime associated to a Cauchon diagram C has been studied recently by Casteels [5] who gave a combinatorial criterion inspired by Lindström's Lemma.

Acknowledgements

The results in this paper were announced during the mini-workshop “Nonnegativity is a quantum phenomenon” that took place at the Mathematisches Forschungsinstitut Oberwolfach, 1–7 March 2009, [31]; we thank the director and staff of the MFO for providing the ideal environment for this stimulating meeting. We also thank Konni Rietsch, Laurent Rigal, Lauren Williams, Milen Yakimov and, especially, our co-author Ken Goodearl for discussions and comments concerning the results presented in this survey paper both at the workshop and at other times. We also thank Natalia Iyudu for the organisation of the Belfast conference in August 2009 at which we presented many of these results.
